Heat recovery
Approximate expression

1. Introduction

Micro combined heat and power plants, especially those operating stand-alone, are subject to variable demand for electricity and heat. The amount of heat which can be recovered from exhaust gas in the heat recovery unit (HRU) depends on: the flow rate and temperature of exhaust gas, the flow rate and temperature of circulating water, and the type and size of HRU. When a specific microturbine is analyzed together with a specific HRU, the determination of heat transfer rate of the HRU for a given electrical output can be greatly simplified. The reason is that for specific environmental parameters the parameters of flue gas exiting the turbine and entering the HRU vary with the load in a strictly defined, unambiguous manner. Therefore there exists a possibility to formulate a function for calculating the heat transfer rate of the HRU, \(Q\), in which the independent variables are limited to: the microturbine electrical power output, \(P_e\), the circulating water mass flow rate, \(\dot{m}_w\), and the circulating water temperature at the inlet to the HRU, \(T_{w1}\).

In this work the following structure of approximate expression for the heat transfer rate of the HRU,

\[
Q = \dot{Q}(P_e, \dot{m}_w, T_{w1})
\]

was established. Such an expression allows an easy and fast calculation of the amount of heat that can be recovered at different microturbine loads. It is a very useful tool for predicting the amount of heat available from HRU for a given electric load characteristics. It facilitates the development of such a strategy for operation of the microturbine-HRU system that will allow coverage of the demand for electricity and/or heat at any time. It is also useful for the variant selection of a microturbine-HRU set for the forecasted time varying demand for electricity and heat.

Coefficients appearing in expression (1) were determined based on the heat transfer rate of the HRU, calculated by the effective NTU method for selected ranges of the microturbine electrical output, the circulating water mass flow rate, and the circulating water inlet temperature to the HRU.

In the literature considerable interest has been devoted to the micro combined heat and power (CHP) plants based on microturbines [1–9] or small internal combustion engines [10–16], operated at part-load. In their works the authors have paid much attention to the problems of exhaust heat recovery. They conducted experimental research [1–3,6,7,12–16] and computational analyses [2,4–6,8–11,16]. The aim of the investigations was to evaluate CHP plants in terms of their performance and energy efficiency [1–16]. In some cases the economic [4,5,8,10,14] or environmental [8,10,14,16] aspects of CHP were emphasized. The experimental works have shown a large impact of the engine load [1,3,6,7,12–15], circulating water flow rate [13], and circulating water temperature [1,12] on the amount of heat recovered in the HRU. In Ref. [3] the
The capacity is calculated on the assumption that the temperature of performance characteristics of CHP microturbines or CHP internal combustion engines was used. Particularly noteworthy are Refs. [4,5,9] in which generalized part-load performance characteristics of CHP microturbines or CHP internal combustion engines are developed. In Refs. [4,5] the CHP heating capacity is calculated on the assumption that the temperature of the flue gas exiting the HRU is in all cases equal to 70 °C. In the case of Refs. [9,11] the heat from the exhaust gas is utilized in a heat recovery steam generator. The part-load performance of the heat recovery steam generator was calculated in this case from special approximate expressions. These expressions concerning steam generators, as to the structure, functions arguments, and potential applications, are similar to those developed for water heaters in the present work.

2. Analysis

2.1. Rigorous model

The analysis comprises two types of commercially produced microturbines with a nominal power of 30 kW. One of them is the Capstone C30 microturbine operating according to a recuperated cycle, and the other is the Capstone 330 based on a non-recuperated cycle. Both turbines are operated at part load by reducing the rotational speed. The analysis is based on two microturbine part-load characteristics: the dependence of exhaust gas mass flow rate and the dependence of exhaust gas temperature.
on the microturbine electrical power output. These characteristics are given, respectively, by Eqs. (2) and (3) for the recuperated microturbine Capstone C30 (REC) and by Eqs. (4) and (5) for the non-recuperated microturbine Capstone 330 (NO REC). They are valid for the ISO ambient conditions (15 °C, 60% relative humidity, 101.325 kPa standard sea level pressure) and steady-state part-load operation. In the development of correlations (2)–(5) the values of exhaust gas mass flow rate and exhaust gas temperature taken from manufacturer’s technical files were used [17,18].

For the REC case

\[
m_{\text{exh}} = 0.09100 + 0.01100 \cdot P_{\text{el}} - 2.325 \times 10^{-4} \cdot P_{\text{el}}^2 + 3.699 \times 10^{-6} \cdot P_{\text{el}}^3 \tag{2}
\]

\[
T_{\text{exh1}} = 2.887 \cdot P_{\text{el}} + 463.1 \tag{3}
\]

For the NO REC case

\[
m_{\text{exh}} = 0.09768 + 0.01242 \cdot P_{\text{el}} - 2.964 \times 10^{-4} \cdot P_{\text{el}}^2 + 4.480 \times 10^{-5} \cdot P_{\text{el}}^3 \tag{4}
\]

\[
T_{\text{exh1}} = 738.1 + 15.44 \cdot P_{\text{el}} - 2.157 \cdot P_{\text{el}}^2 + 0.1873 \cdot P_{\text{el}}^3 - 0.01020 \cdot P_{\text{el}}^4 + 3.331 \times 10^{-4} \cdot P_{\text{el}}^5 - 5.933 \times 10^{-6} \cdot P_{\text{el}}^6 + 4.418 \times 10^{-8} \cdot P_{\text{el}}^7 \tag{5}
\]

In the correlations given by Eqs. (2)–(5) \( P_{\text{el}} \) [kW] ranges from 2 kW to 30 kW, \( m_{\text{exh}} \) is expressed in [kg/s], and \( T_{\text{exh1}} \) in [K]. The relative errors of approximations do not exceed 3% at any data point.

Analyzed cases of the microturbine-HRU sets are listed in Table 1. Table 2 shows the data on the examined HRUs. Schematic bundle structure is shown in Fig. 1. Using the part-load characteristics of microturbines given by Eqs. (2)–(5) and the geometrical characteristics of the heat exchangers, values of the convection heat transfer coefficient on the exhaust gas side surface of the HRU were calculated for different loads. For the case of wavy fins the following correlation proposed by Wang et al. [19] was used.

\[
\dot{h}_H = 0.882 \cdot \frac{R_{D_h}}{R_{D_w}} \left( \frac{D_e}{D_h} \right)^{0.53} \left( \frac{S}{P_f} \right)^{0.49} \left( \frac{S}{P_f} \right)^{-0.58} \tan(\theta)^{-0.2} \tag{6}
\]

</table>

* Types of HRUs are specified in Table 2.
For \( \text{Re}_{\text{DC}} \geq 1000 \)

\[
J_{H} = 0.0646 \; \text{Re}_{\text{DC}}^0 \cdot \left( \frac{D_{c}}{D_{h}} \right)^2 \cdot \left( \frac{s}{P_{t}} \right)^{1.03} \cdot \left( \frac{P_{t}}{D_{c}} \right)^{0.432} \cdot \tan(\theta)^{-0.692} \cdot N^{-0.737}
\]

(10)

where

\[
J_{1} = -0.0545 - 0.0538 \cdot \tan(\theta) - 0.302 \cdot N^{-0.24} \cdot \left( \frac{s}{P_{t}} \right)^{-1.3}
\]

\[
\cdot \left( \frac{P_{t}}{P_{l}} \right)^{0.379} \cdot \left( \frac{P_{l}}{D_{h}} \right)^{-1.35} \cdot \tan(\theta)^{-0.256}
\]

(11)

\[
J_{2} = -1.29 \left( \frac{P_{l}}{P_{t}} \right)^{1.77 - 9.43 \cdot \tan(\theta)} \cdot \left( \frac{D_{c}}{D_{h}} \right)^{0.229 - 1.43 \cdot \tan(\theta)} \cdot N^{-0.166 - 1.08 \cdot \tan(\theta)} \cdot \left( \frac{s}{P_{t}} \right)^{-0.174 \cdot \ln(0.5 \cdot N)}
\]

(12)

Hydraulic diameter \( D_{h} \) is defined as

\[
D_{h} = 4 \cdot A_{\text{min}} / L / A
\]

(13)

These expressions are valid for

\[
\text{Re}_{\text{DC}} = 300 - 10,000
\]

\[
D_{c} = 7.66 - 16.85 \text{ mm}
\]

\[
P_{t} = 21 - 38.1 \text{ mm}
\]

\[
P_{l} = 12.7 - 33 \text{ mm}
\]

\[
F_{p} = 1.21 - 6.43 \text{ mm}
\]

\[
N = 1 - 6
\]

\[
\theta = 5.3 - 18.5\degree
\]

\[
X_{f} = 3.175 - 8.25 \text{ mm}
\]

In the case of correlations (6) and (10) the errors do not exceed \( \pm 15\% \) for 91.3\% of measuring points. For plain fins the correlation by Gray and Webb [20] was applied

\[
J_{H} = 0.14 \; \text{Re}_{\text{DC}}^{0.328} \cdot \left( \frac{P_{t}}{P_{l}} \right)^{-0.502} \cdot \left( \frac{s}{D_{c}} \right)^{0.0312}
\]

(14)

The correlation (14) is applicable for

\[
N = 1 - 8 \text{ or more}
\]

\[
\text{Re}_{\text{DC}} = 500 - 24,700
\]

\[
P_{t}/D_{c} = 1.97 - 2.55
\]

\[
P_{l}/D_{c} = 1.70 - 2.58
\]

\[
s/D_{c} = 0.08 - 0.64
\]

The errors of correlation (14) do not exceed \( \pm 10\% \) for 89\% of measuring points. The Colburn number for heat transfer in Eqs. (6), (10) and (14) is expressed as

\[
J_{H} = \frac{\text{Nu}_{\text{exh}}}{\text{Re}_{\text{DC}} \cdot \text{Pr}_{\text{exh}}^{1/3}}
\]

(15)

For selected circulating water mass flow rates and selected circulating water inlet temperatures the convection heat transfer coefficients for water were calculated using the following Gnielinski correlation [21]

\[
\text{Nu}_{\text{w}} = \frac{(\text{Re}_{\text{Di}} - 1000) \cdot \text{Pr}_{\text{w}} \cdot f_{w}(2)}{1 + 12.7 \cdot \sqrt{(f_{w} / 2) \cdot (\text{Pr}_{\text{w}}^{2/3} - 1)}}
\]

(16)

where

\[
\text{Nu}_{\text{w}} = \frac{h_{w} \cdot D_{i}}{k_{w}}
\]

(17)

and

\[
f_{w} = (1.58 \cdot \ln(\text{Re}_{\text{Di}}) - 3.28)^{-2}
\]

(18)

The correlations (16) and (18) are applicable for [21]

\[
\text{Pr}_{\text{w}} = 0.5 - 2000
\]

\[
\text{Re}_{\text{Di}} = 3000 - 5,000,000
\]

The errors of correlation (16) do not exceed \( \pm 10\% \). The errors of correlation (32) due to the errors of correlations (6), (10), (14) and (16) do not exceed \( \pm 5\% \). For the flow inside the tubes, the
characteristic dimension is the tube inside diameter $D_t$. The overall heat transfer coefficient is calculated from the equation below

$$UA = \left( \frac{1}{h_w A_1} + \frac{\delta_{\text{wall}}}{k_{\text{wall}} A_{\text{wall}}} + \frac{1}{\eta_s h_{\text{exh}} A} \right)^{-1} \quad (19)$$

where

$$A_{\text{wall}} = (A_e - A_1)/\ln(A_e/A_1) \quad (20)$$

The extended surface efficiency, $\eta_s$, was determined according to the standard procedure shown below.

$$\eta_s = 1 - \frac{A_t}{A} \left( 1 - \frac{1}{\eta_f} \right) \quad (21)$$

where

$$\eta_f = \frac{\tan(m \cdot r \cdot \phi)}{m \cdot r \cdot \phi} \quad (22)$$

$$m = \sqrt{\frac{2}{h_{\text{exh}}}} \quad (23)$$

$$\phi = \left( \frac{R_{\text{eq}}}{r} - 1 \right) \left[ 1 + 0.35 \cdot \ln \left( \frac{R_{\text{eq}}}{r} \right) \right] \quad (24)$$

$$R_{\text{eq}} = 1.27 \frac{P_1}{2} \left( \frac{\left( \frac{P_1}{2} \right)^2 + P_2^2}{P_1} - 0.3 \right)^{1/2} \quad (25)$$

Using the $\varepsilon$-NTU method, the heat exchanger performance was computed for selected combinations of input data. In the cases where the number of rows of tubes was greater than 6, the $\varepsilon$-NTU relationship for pure countercflow heat exchanger was applied [20]

$$\varepsilon = \frac{1 - \exp \left[ -\text{NTU} \cdot (1 - C^*) \right]}{1 - C^* \cdot \exp \left[ -\text{NTU} \cdot (1 - C^*) \right]} \quad (26)$$

Otherwise, for $N \leq 6$, the following expression was used [20]

$$\varepsilon = 1 - \exp \left\{ \frac{\text{NTU}^{0.22}}{C^*} \left[ \exp \left( -\frac{C^*}{\text{NTU}^{0.78}} \right) - 1 \right] \right\} \quad (27)$$

The heat capacity ratio in Eqs. (26) and (27), $C^*$, is defined as:

$$C^* = C_{\text{min}}/C_{\text{max}} \quad (28)$$

and is in the range from 0 to 1. The NTU is calculated as

$$\text{NTU} = UA/C_{\text{min}} \quad (29)$$

The effectiveness of heat exchanger, $\varepsilon$, is defined as

$$\varepsilon = \frac{Q}{Q_{\text{max}}} \quad (30)$$

The maximum possible heat rate thermodynamically possible, $Q_{\text{max}}$, is calculated from

$$Q_{\text{max}} = C_{\text{min}} \left( T_{\text{exh}} - T_{w1} \right) \quad (31)$$

The effectiveness of the HRU given by Eqs. (26) and (27) is the greater the smaller is $C^*$. For a given value of $C^*$ the effectiveness increases asymptotically with the increase of NTU to a constant value. The HRU effectiveness determined from Eq. (26) or (27) is used to calculate the actual heat transfer rate $Q$ from Eq. (30).

The data used in the calculations were included in the ranges

$$P_{\text{el}} = 2 - 30 \, \text{kW}$$

$$T_{w1} = 308.15 - 343.15 \, \text{K}$$

$$m_w = 750 - 11,000 \, \text{kg/h}$$

Thermophysical properties of fluids were determined for the mean temperature of the inlet and outlet of the exchanger. The temperature-dependent thermal conductivity of stainless steel AISI316, the heat exchanger material, was calculated from linear interpolation between the two values: 15.0 W/(m K) for 20 °C and 17.5 W/(m K) for 200 °C [22]. The thermal conductivity of copper was taken constant of 380 W/(m K). Thermophysical properties of water and exhaust gas were based on the data from Ref. [23]. The calculations assumed that the exhaust gas had properties of dry air with molar composition 78.12% N₂, 20.96% O₂ and 0.92% Ar. Due to the large excess air ratio (about 7.8 for REC and about 4.2 for NO REC at rated power, and even more at part-load) the effect of presence of combustion products on the thermophysical properties of the working medium is negligibly small, namely maximum of 2.00% difference in specific heats for REC and of 2.93% for NO REC case at ISO ambient conditions and at nominal power for which excess air ratio is minimal and the influence of combustion products is the greatest.

Influence of ambient temperature variation on the HRU performance may be included by introducing a correction factor, in case of availability of relevant data. Ambient temperature effect on the performance of HRU no. 8 (Table 1) has been tested for the rated power on the basis of data from Ref. [17]. The rise in ambient temperature of 5 K results in the 3% increase in the HRU performance, while the drop in ambient temperature of 5 K causes a decrease of the HRU performance by 5%. Overall, an increase in ambient temperature contributes to the HRU performance increase.

The backpressure effect resulting from the exhaust gas flow through the HRU is omitted as having no significant effect. Maximum pressure drop in the HRU is of magnitude of 300 Pa at the nominal power of microturbine. Such a pressure drop results in 0.4% decrease of power and 0.3% decrease of electrical efficiency [17]. Measurements of impact of backpressure on microturbine exhaust temperature [7] revealed that it is unnoticeable.

During normal operation of a microturbine it is not possible to recover the latent heat of the water vapor contained in the flue gas. Even when a natural gas is combusted in air taken from the ambient of temperature 35 °C fully saturated with moisture, the dew point temperature of the exhaust gas equals 41.5 °C for REC and 45.6 °C for NO REC. The present analysis was carried out for ISO ambient conditions and natural gas as a fuel. For such a case the dew point temperature of the exhaust gas drops to 27.1 °C and 35.3 °C for REC and NO REC, respectively. The lowest considered temperature of water at the exchanger inlet was 35 °C. The exhaust gas could not reach this temperature, so the condensation heat was not taken into account in the calculations. The excess air ratio is the larger the smaller the power developed by the microturbine, therefore at part load the dew point temperature is even lower.
2.2. Regression analysis

The structure of the formula which approximates the dependence of the heat transfer rate of the HRU on the microturbine electrical output, the circulating water mass flow rate, and the circulating water inlet temperature was established by heuristic trial and error procedure. The effect of each independent variable on the HRU performance was examined. Many different mathematical formulas were tested while searching for a single universal function which is flexible, has as few coefficients as possible and gives results of acceptable accuracy. We started from a linear function with four coefficients, but the results were unsatisfactory. We gradually increased the number of correlation coefficients and correlation non-linearity until the accuracy criteria we had established were met.

The following approximating function was selected

$$ Q = e + a \cdot (P_{el} + b)^/C0 \cdot T_{w1}^d - f \cdot P_{el} \cdot m_{w}^c $$

(32)

In correlation (32) $P_{el}$ should be expressed in [kW], $T_{w1}$ in [K], and $m_{w}$ in [kg/h]. To determine coefficients in Eq. (32) the following objective function was minimized

$$ S = \sum_{i} w_i \cdot \left| Q - Q_i \right| / Q_i $$

(33)

where $Q_i$ is the heat transfer rate determined by the $\varepsilon$-NTU method for the $i$-th data set, $Q$ is the heat transfer rate calculated from the approximate formula for the same data, and $w_i$ is a weighting factor. The weighting factors $w_i$ were used to reduce the maximum deviation of approximate values from the corresponding theoretical ones. For each considered case of a specific microturbine-HRU set, about 3000 points were used to determine the values of coefficients of the approximate expression. Calculations were performed using MathCAD 15.0 software. The values of coefficients in Eq. (32) for all investigated microturbine-HRU sets are given in Table 3. Relative approximation errors do not exceed 1.50% for 80% of the points. Larger errors occur for the smallest and largest values of $P_{el}$, $T_{w1}$ and $m_{w}$. The maximum relative error of any data point is 3.22%. The total error including the errors of correlations for heat transfer coefficients and approximation errors in Eq. (32) does not exceed 8.08% for all data points and 6.44% for 80% of the points. The RMS error for regression is calculated as

$$ \text{RMS} = \sqrt{\frac{\sum_{i=1}^{n} (Q - Q_i)^2}{n}} $$

(34)

RMS was determined separately for each case. The maximum value of RMS occurred in case 10 and was equal to 1.34 kW.

When instead of the water mass flow rate, $m_{w}$, the water outlet temperature, $T_{w2}$, is an input together with $P_{el}$, $T_{w1}$, the procedure of determining the thermal performance of the HRU, $Q$, is as follows. From the equation

$$ m_{w} + C_{1} \cdot m_{w}^c - C_{2} = 0 $$

(35)

$m_{w}$ is determined, and then from the equation

$$ \dot{Q} = m_{w} \cdot q / 3600 $$

(36)

$\dot{Q}$ is calculated, where

$$ q = c_{w} \cdot (T_{w2} - T_{w1}) $$

(37)

Coefficients $C_{1}$ and $C_{2}$ are calculated, respectively, from the following relationships

$$ C_{1} = \frac{3600 \cdot f \cdot P_{el}}{q} $$

(38)

$$ C_{2} = \frac{3600 \cdot [e + a \cdot (P_{el} + b)^/C0 \cdot T_{w1}^d]}{q} $$

(39)

In Eqs. (35)-(39) $P_{el}$ and $q$ are expressed in [kW], $q$ in [kJ/kg], $m_{w}$ in [kg/h], $c_{w}$ in [kJ/(kg·K)], temperatures in [K] and coefficients $a-g [-.]$.

3. Sample calculations

Sample calculations were performed to illustrate accuracy of the approximate expression and to demonstrate its usefulness for conducting various analyses of part-load performance of the microturbine-HRU sets.

Figs. 2–4 show the dependence of the heat transfer rate of the HRU to the circulating water, $Q$, on the microturbine electrical power output, $P_{el}$, for particular cases of microturbine-HRU sets and selected inlet temperatures, $T_{wi}$, and flow rates, $m_{w}$, of the circulating water. The lines represent values calculated from the approximate expression given by Eq. (32), the points represent exact values determined by the $\varepsilon$-NTU method. Agreement of the results is very good.

As seen in the figures, the amount of heat recovered in the heat exchanger, $Q$, decreases with decreasing load, i.e., the decrease of electrical power from 30 kW to 2 kW results in the heat transfer rate reduction by a factor of 2.4–2.8 in the case of NO REC and of 3.5–4.2 in the case of REC. Reduction of $Q$ is the greater the larger the surface of heat exchanger and the higher coefficients of heat transfer. For the REC cases, the heat transferred in the HRU depends almost linearly on load. In the NO REC case the heat transferred in the HRU is from 2.3 (high load) to 3.4 (low load) larger than in the REC case. The NO REC case yields higher thermal power because the

exhaust gases are not cooled in the internal recuperator and thus their temperature at the HRU inlet is higher. Moreover, in this case the exhaust gas mass flow rate is higher. The differences between the HRU performance profiles for REC and NO REC cases are due to differences in part-load characteristics of the REC and NO REC turbines as well as they result from different parameters of the exhaust gas for two cases under consideration.

The differences between the heat transfer rates for various water flow rates, numbers of tube rows in the exchanger, types of fins decrease with decreasing load. This follows from the fact that at low electrical loads, where the exhaust gas rates and its temperatures are low, the effectiveness of HRU, $\epsilon$, is relatively high. In such cases the heat transfer rate is approximately equal to $Q_{\text{max}}$ given by Eq. (31).

Lowering the temperature of water entering the heat exchanger (Fig. 2) as well as increasing the water rate (Fig. 3) or heat transfer surface (Fig. 4) results in increasing the heat transfer rate. For example, an increase of heat transfer surface of the heat exchanger with plain fins by 50%, from 8 to 12 tube rows, is followed by 14% increase of $Q$ in the REC case at full electrical load.

As seen in Fig. 4, the copper wavy-fin HRU is more efficient than the stainless steel plain-fin HRU. It is mainly due to strongly reduced fin effectiveness resulting from low thermal conductivity of stainless steel.

![Fig. 3. Heat transfer rate of eight-row plain fin HRU (cases no. 2 and 5) versus electrical power for various water mass flow rate at inlet water temperature of 323.15 K (points – calculated data; lines – approximation result).](image)

![Fig. 4. Heat transfer rate of various HRUs versus electrical power at water mass flow of 5000 kg/h and inlet water temperature of 323.15 K (circles, squares – calculated data, lines – approximation result; solid lines and circles – plain fins, dashed lines and squares – wavy fins).](image)

![Fig. 5. Heat transfer rate of four-row wavy-fin HRU (cases no. 7 and 9) versus electrical power for various outlet water temperatures at inlet water temperature of 313.15 K.](image)
Fig. 5 displays the dependence of $Q$ on $P_{el}$ for the case where the water outlet temperature, $T_{w2}$, is used as an input parameter instead of the water mass flow rate, $m_w$. An increase in water outlet temperature results in a decrease of heat transfer rate because in this case the mean temperature difference and the water side heat transfer coefficient decrease. Data for Fig. 5 were calculated using the algorithm presented by formulas (35)–(39).

4. Conclusions

The performed analysis has shown that it is possible to formulate a versatile approximate expression, $Q = Q(P_{el}, m_w, T_{w1})$, for calculation of heat transfer rate of the heat recovery unit, which is valid for various microturbine-HRU sets. Extension of the applicability of the proposed function for other sets than investigated in the work requires determining appropriate coefficients, which is a laborious task. Moreover, for other microturbine-HRU sets the function structure may not be optimal with respect to accuracy. In such cases the function structure should be adjusted to better fit the calculated data. Once the coefficients of correlation are calculated, the prediction of the amount of available heat at different loads can be done quickly and easily.

Fig. 2 shows that at low loads the HRU performance does not depend much on the circulating water mass flow rate. It therefore can be concluded that it is reasonable to reduce the circulating water flow along with decreasing load. In this way the pumping work is decreased with only slight reduction of transferred heat. The results of analysis show that the exchanger designed for a nominal load is also suitable for partial load.
